I. Intro

I. Presenting the GVAR Methodology

Following Mauro and Pesaran (2013, 14), we define a country-specific GVAR model as follows,

$$\mathbf{x}_{it} = \alpha_{i,0} + \Phi_{i1}\mathbf{x}_{i,t-1} + \Phi_{i2}\mathbf{x}_{i,t-2} + \Lambda_{i0}\mathbf{x}_{it}^{*} + \Lambda_{i1}\mathbf{x}_{i,t-1}^{*} + \Lambda_{i2}\mathbf{x}_{i,t-2}^{*} + \mathbf{u}_{it}$$
(1)

where \mathbf{x}_{it} is a $k_i \times 1$ vector of domestic variables, \mathbf{x}_{it}^{\star} is a $k_i^{\star} \times 1$ vector of foreign variables, and \mathbf{u}_{it} is a serially uncorrelated and cross-sectionally weakly dependent process. The inclusion of the weighting foreign variables \mathbf{x}_{it}^{\star} is one of the main characteristics of the GVAR approach. In our case, the vector of foreign variables is a single variable, namely, bilateral trade. Using this variable, a square weighting matrix was constructed. If there are 30 countries, the weight matrix has 30 rows and 30 columns—its diagonal element contains only zeros. Every country is weighted by the other 29 remaining countries. Finally, in our case, the vector \mathbf{x}_{it} containing the domestic variables considers military personnel and iron production.
